2.3 The WikiText concept 1

The WikiText is a markup language, created especially for the requirements of the TiddlyWiki application. It is based on Markdown¹, but extended with some TiddlyWiki specific features. On one hand its a text-to-HTML conversion language and on the other hand its used to provide the interactive features of TiddlyWiki. The aim of this language is to allow the user of the software to focus on the writing. [TID09] The WikiText is used to format Tiddlers within the TiddlyWiki application. The tags of the WikiText syntax can be used within the standard text input field. During the saving process these tags renders to HTML elements for example:

```
1 WikiText:---
2 Renders as:
3 HTML:<hr>
4 WikiText:[img[http://tiddlywiki.com/favicon.ico]]
5 Renders as:
6 HTML:
```

Listing 1: Example use of WikiText

Furthermore the WikiText is used to access the widgets which are integrated in the application. These widgets are used to enhance the the WikiText with a rich functionality. Widgets are based on the HTML-Syntax but always starts with a \$.

```
1 WikiText:
2 <$button message="tw-close-tiddler">Close Me!</$button>
```

Listing 2: Example use of widgets within WikiText

3 Bootstrap-Process 2-3

3.1 The Heart of TiddlyWiki (Boot-Kernel) 1 - 1.5

3.2 Timeline of the startup Process 1 - 1.5

4 The Plugin and Module concept 4-5

4.1 Introduction to the Plugin-Concept 1

4.2 Kernel-Plugins 1

4.3 UI-Elements 1

4.4 Developing a own Plugin 1-2

5 The TiddlyWiki data management concept 2-3

This section describes how the data of the wiki is stored within Tiddlywiki during the runtime. And how the complete wiki is persisted.

5.1 Data Management during Runtime 1-2

During the runtime the data of Tiddlywiki is stored in javascript objects. These objects are synchronized with the DOM-Representation of Tiddlywiki. This means every change of the original data of a Tiddler, fires an event which changes all DOM-Representations of the Tiddler and the javascript object. The barbone Wiki store is created during the boot process and is kept in a object called \$tw.Wiki. This object contains amongst others a hashmap of the different Tiddlers of Tiddlywiki. The Hashmap is used to store the javascript object representation of the different Tiddlers.

5.2 Data Persistence 1

Persist data

TiddlyWiki supports a wide range of methods to persist your data. One of this methods is the HTML5 fallback saver. This methods works on almost every browser. With this method a copy of the entire wiki will be downloaded by the browser. This means you get a new file everytime you hit the save button. To avoid this there are some plugins for different browsers to allow to save direct to the current open TiddlyWiki-File.

Data-Storage

TiddlyWiki persists the data within the HTML-File in two Div-Areas depending on whether the encryption of the TiddlyWiki is activated or not. If the TiddlyWiki is not encrypted the data is stored in the Div-Area called “StoreArea”. Every created Tiddler is stored in a own Div-area with a few custom values. An example of a saved Tiddler is shown below (Listing 3). The Div-Area has the following attributes, all attributes which are not in these list are parsed as a custom field:

created Timestamp number of milliseconds since 01.01.1970.

modified Timestamp number of milliseconds since 01.01.1970.

tags list of tags separated by whitespace. Tags which contain whitespaces are wrapped by [[]], e.g. [[example Tag]].

type Type of the Tiddler.

title Title of the Tiddler

```
1 <div created="20140611153703343" modified="
   20140611153734589" tags="testTag" testfield="
   testvalue" title="TestTiddler" type="text/plain">
2     <pre>testText</pre>
3 </div>
```

Listing 3: Data-Div

With a activated encryption the data is stored in a special Div-Area called “encryptedStoreArea”. TiddlyWiki uses the Stanford JavaScript Crypto Library². The encrypted Tiddlers are saved in a JSON string within this Div-Area.
